Home Appliance Efficiency

Home Appliance Efficiency

Smart appliances can communicate their energy usage in real-time. Heating and cooling systems (like ACs) typically consume the most power in a household. Setting your AC thermostat to 24°C (75°F) instead of 20°C (68°F) can save up to 20% on cooling costs. Standby power, or 'vampire draw', can account for up to 10% of a home's energy use; smart plugs can completely cut off power to idle electronics.

Maximizing Solar with Appliances:

Energy-efficient appliances synergize perfectly with solar energy systems. By scheduling heavy-load appliances (like dishwashers, washing machines, and pool pumps) to run during peak solar production hours (typically 10 AM to 2 PM), you can directly consume the free electricity generated by your roof. This strategy, known as solar self-consumption, significantly reduces your reliance on grid electricity and speeds up the payback period of both the appliances and the solar panels.
